Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

Description

TECHNICAL FIELD

[0001] This invention relates to apparatus for holding a compact disk.

[0002] By "compact disk", in the context of this specification, is meant not only the relatively common standard 120mm diameter laser-readable disk such as are currently sold carrying, for example, pre-recorded music, computer software and data, and similar recordable disks, but also similar disks of various sizes such as are known or proposed for recording video, films, interactive games and other information or data.

BACKGROUND ART

[0003] Conventionally, when not in use, such compact disks are stored in clear polystyrene boxes, known as "jewel cases", wherein the disk is held on a separate insert or tray fitted in the case and having seven or eight tines arranged to form a boss or "rosette" with which the aperture in the centre of a compact disk may be releasably engaged.

[0004] The legs or tines of the rosette are shaped such that they extend upwardly from the tray, curve outwardly, such that they can grip a compact disk, and then, towards their ends, curve inwardly to provide a boss over which the hole in the compact disk may be manually pushed.

[0005] It has long been recognised that such apparatus for holding a compact disk is not very satisfactory as it requires two hands to release a disk and lift it from the rosette; consequently many people do not attempt to push the centre of the rosette but instead use just one hand to grasp an outer edge of a compact disk and wrench it off the rosette thereby bending the disk, sometimes scoring the recorded surface of the disk on the tines, and eventually distorting or even breaking the tines. Such apparatus also does not retain the disk securely in that the disk can be released by lifting an edge thereof and may also be released due to shock loads, e.g. during transport, rough handling or if the apparatus is dropped or is subjected to an impact.

[0006] GB-A-2291640, which is used for the delimitation of claim 1, and WO96/14636, which is state of the art under Article 54 (3) EPC, disclose apparatus which overcomes many of the disadvantages of the prior art and the disclosure of both GB-A-2291640 and WO96/14636 is hereby incorporated in the present specification.

[0007] It has, however been found that the apparatus disclosed in GB-A-2291640 and WO96/14636 can be further improved and that its construction can be further simplified.

[0008] One of the aims of the invention is to inhibit users from attempting to remove the disk by gripping the edge of the disk without having depressed the release

mechanism.

[0009] Another aim is to reduce the risk of accidental release of a disk due to shock loads applied in the plane of the disk.

[0010] In conjunction with the above, still another aim is to facilitate easy removal of a disk after the release mechanism has been depressed.

DISCLOSURE OF INVENTION

[0011] According to the invention, there is provided an apparatus for holding a compact disk having a central hole, the apparatus comprising: a base portion provided with disk engaging and release means for releasably engaging the central hole of a disk; ejection means for moving the disk to a raised position relative to the base portion following its release from the disk engaging means; characterised by an upstand for surrounding the periphery of a disk held on the apparatus, the upstand being positioned and shaped to allow access to the edge of the disk when it has been moved to the raised position following release from the disk engaging means to permit removal of the disk from the apparatus but prevent such access when the disk is held by the disk engaging means.

[0012] Other features of the invention will be apparent from the following description and from the subsidiary claims of the specification.

BRIEF DESCRIPTION OF DRAWINGS

[0013] The invention will now be further described, merely by way of example, with reference to the accompanying figures, in which:

Figure 1 is a schematic plan view of a known release mechanism as described in GB-A-2291640;

Figure 2 is a plan view of a first embodiment of apparatus according to the present invention;

Figure 3 is a side cross-sectional view through the apparatus of Figure 2 with a disk showing held thereon;

Figures 4A - 4D are schematic plan views of alternative forms of release mechanism which may be used in place of that shown in Figure 2;

Figure 5 is a schematic plan view of part of apparatus such as that shown in Figure 2 showing a modification thereof;

Figures 6A and 6B are sectional views taken along line A-A of Figure 5;

Figure 7 is a plan view of apparatus similar to that shown in Figure 2 but with the modification illustrat-

ed in Figure 5;

Figure 8 is a plan view of another embodiment of apparatus according to the present invention;

Figure 9 is a perspective view of the apparatus shown in Figure 8;

Figure 10 is a plan view of a further embodiment of apparatus according to the present invention;

Figure 11 is a perspective view of the apparatus shown in Figure 10;

Figure 12 is a plan view of an alternative form of release mechanism which may be used in the apparatus shown in the preceding figures;

Figure 13A is a perspective view of the release mechanism of Figure 12; and

Figure 13B is a similar view but with some parts omitted so as to reveal other parts which are concealed in Figure 13A.

BEST MODE OF CARRYING OUT THE INVENTION

[0014] Figure 1 shows a plan view of two disk engaging arms 1 of prior art such as that disclosed in GB-A-2291640, cantilevered from a base portion 2 and connected thereto at hinge lines 3. The inner end of each arm is provided with a semicircular contact portion 4 which together form a substantially circular button-like member over which the central aperture of a disk (not shown) is fitted. Each contact portion 4 carries a lip or projection 4A for securely retaining a disk by engaging on an outwardly facing surface thereof. The disk is released by depressing the button-like member towards the base portion which causes the contact portions 4 and hence the projections 4A to move towards each other until the engagement of the projections 4A on the disk is released.

[0015] Although this release mechanism functions satisfactorily, it can be improved in a number of ways, particularly to reduce the risk of accidental release of the disk therefrom.

[0016] One problem with the apparatus shown in Figure 1 is that if a force is applied in the plane of the disk in the direction A, i.e. perpendicular to the arms 1, this force causes the disk to engage both contact portions and apply forces to them as illustrated by the arrows B. Such forces tend to push both contact portions 4 inwardly, i.e. towards each other, and downwardly (towards the base portion 2) with the result that the disk can be released. In the example shown in Figure 1, the gap between the contact portions is relatively small but in real life the gap may be much wider so making this problem worse. This is a significant disadvantage as forces can

be applied in the direction A due to mishandling of the disk or shock loads, e.g. if the apparatus is dropped or receives a blow on the side.

[0017] It should be noted that references in this specification to forces applied to a disk include not only forces applied directly to the disk but also inertial forces which cause the disk to move in a similar way, e.g. when the apparatus is subjected to an impact.

[0018] It has been discovered that one way of reducing the possibility of the disk being released in this way is to arrange the contact portions 4 so that at least the majority of any force applied in the direction A is transmitted by the disk to only one of the contact portions 4.

[0019] This can be achieved by arranging the contact portions 4 so that the ends of the gap between them lie away from the perpendicular to the length of the arms 1.

[0020] Figures 2 and 4 show various possible shapes of the contact portion 4 which achieve this.

[0021] There are a number of reasons why such an arrangement of the contact portions helps reduce the risk of the disk being released by forces applied within the plane of the disk and, in particular, in a direction perpendicular to the length of the arms 1. Firstly, as the force (or at least a majority of the force) A acts on only one of the contact portions, the tendency for the contact portions to be squeezed together is avoided or reduced. Also, as the gap between the contact portions 4 does not lie on this perpendicular, the contact portions can be formed to be a very close fit within the disk aperture in this direction so as to reduce the scope for lateral movement of the disk in this direction to a minimum.

[0022] Furthermore, if a force is applied in direction C shown in Figure 4A, i.e. at the end of the gap between the contact portions 4, the tendency for such a force to cause the disk to release compared with a force in direction A acting on the arrangement shown in Figure 1 is much reduced. Again, there are a number of reasons for this. As the gap between the contact portions is no longer perpendicular to the length of the arms 1, the width of the gap can be reduced as the inward movement of the contact portions 4 when the button-like member is depressed will be in a direction at an angle across the gap. The consequent reduction in the width of the end of the gap where the force C may be applied reduces the pinching effect of such a force as well as reducing the scope for movement of the disk perpendicular to the gap. Furthermore, a force in direction C will have a much reduced tendency to deflect the arm 1 as it is no longer perpendicular to the length of the arm 1. A force in direction C is resisted by the arm 1 as one component of the force is trying to stretch the arm. Furthermore, a force in direction C also acts to hold the disk more tightly under the projection 4A on that side of the button-like member and so the disk is retained more securely rather than having a tendency to be released.

[0023] It will be appreciated that the projections 4A are only provided on the side of the contact portion 4 in line with the arms 1 so they move inwardly when the

button-like member is depressed to release the disk. For this reason, the prior art arrangement shown in Figure 1 is particularly vulnerable to a force applied in the direction A as such a force has no component which acts to hold the disk under either of the projections 4A.

[0024] As mentioned above, the contact portions 4A can have a variety of shapes to achieve the above advantages. The gap between the contact portions may be a simple straight line at, for example, approximately 45-70 degrees to the length of the arms 1 as shown in Figure 4A. Alternatively, the dividing line between the contact portions 4 may have a curved or sinusoidal shape. Figures 2 and 4B show examples of the latter where the contact portions 4 have a shape resembling the "yin-yang" symbol. The ends of these dividing lines still lie away from the perpendicular to the length of the arms 1 and are preferably positioned as close as possible to the arms 1.

[0025] Figure 4C shows a further arrangement in which the dividing line is substantially V or U-shaped and Figure 4D shows a further variant of this in which the dividing line follows a more curved form.

[0026] The width of the gap between the contact portions 4 is preferably 1.5mm or less and most preferably 1.0mm or less.

[0027] A further advantage of the arrangements described above is that the contact portions can be arranged to increase the likelihood that both portions are contacted when the button-like member is engaged by a finger tip (and so give more reliable operation of the disk release mechanism). If the diagonal dividing line shown in Figure 4A is arranged in the orientation shown so that it extends from the top left to the bottom right when a case incorporating the apparatus is open in the orientation shown in Figure 2, a right-handed person tends to extend their right index finger in a similar direction to this diagonal line so their finger tip will usually bridge the dividing line.

[0028] The other shape contact portions 4 shown in Figures 2 and 4B-4D are also designed so that, with a typical adult finger, it is difficult to press the button-like member without engaging both contact portions.

[0029] A yet further advantage of the arrangements described above, is that the dividing line between the contact portions, particularly in the central region of the button-like member, is no longer perpendicular to the length of the arms 1 so any tendency for a finger pressing the button-like member to be pinched by the gap as the contact portions 4 move towards each other is reduced. It will be appreciated that in the arrangements shown in Figures 4C and 4D, the dividing line does not pass across the central region of the button-like member so the possibility of the finger being pinched in this way is further reduced.

[0030] In addition to the above features, it is important to accurately form the button-like member so that it is a close fit within the central aperture of the disk (which has a 15mm diameter in the conventional 120mm diam-

eter disk) in order to minimise the scope for movement of the disk within the plane of the disk whilst it is held on the apparatus. To this end, in the direction parallel to the length of the arms 1, the diameter of the button-like member immediately beneath the projection 4A when the disk is held thereon is preferably as close a match as possible to the diameter of the disk's aperture (which is typically 15mm) so as to avoid or minimise any play therebetween and avoid or minimise any stress applied to the aperture. Preferably the disk is free to rotate on the button-like member although lateral movement of the disk, i.e. within the plane of the disk, on the button is prevented or minimised.

[0031] In the direction perpendicular to the length of the arms 1, the contact portions 4 are again sized to be as close a fit as possible within the aperture of the disk so as to avoid or minimise the scope for movement of the disk in this direction and avoid or minimise any stress applied to the aperture.

[0032] The projections 4A preferably project from the sides of the contact portions and preferably project therefrom by between 0.5 and 1.0mm. Each projection also preferably extends around an arc on the edge of the respective contact portion so as to subtend an angle of between 30 and 90 degrees at the centre of apparatus.

[0033] The apparatus described herein has a number of other important differences over the apparatus described in GB-A-2291640.

[0034] GB-A-2291640 describes the use of resilient ejection means for urging the disk out of engagement with the disk engaging means when the rims or lips release their engagement on the disk, for example, further arms resiliently cantilevered from the base portion or one or more pieces of compressible material.

[0035] Such resilient ejection means may be used in the apparatus described herein. However, instead of or in addition to such resilient means, it has been discovered that the resilience of other parts of the apparatus, e.g. the arms 1 or the base portion 2, and, in particular, the resilience of the disk itself can be used to provide a similar ejection function. The apparatus is thus preferably arranged so that as the button-like member is depressed to release the disk, part of the apparatus and/or the disk is flexed so that elastic energy is stored therein and, when the engagement of the projections 4A is released, the said part and/or disk reverts to its unstressed state and causes at least the central portion of the disk to move so the projections 4A pass through the central aperture of the disk.

[0036] One simple way of achieving this is to provide supports 5 adjacent the periphery of the disk so that when the button-like member is depressed, the disk is moved towards the base portion 2 until its periphery engages the supports 5. Further depression of the button-like member to release the disk thus presses the centre of the disk towards the base portion 2 relative to the periphery of the disk whereby the disk undergoes elastic

deformation. Once the projections 4A have moved inwardly sufficient to release their engagement on the outwardly facing surface of the disk, the disk is free to revert to its unstressed, flat shape whereupon the central portion of the disk moves, or "pops up", so it is not re-engaged by the projections 4A or button-like member when the user's finger is removed.

[0037] In the embodiment shown in Figure 2, support is provided at the periphery of the disk by raised surfaces 5 formed on the base portion 2.

[0038] The arrangement is preferably such that when a disk is held in the apparatus, the arms 2 support the disk clear of the support 5. The disk is thus held in an unstressed state and is free to rotate on the button-like member. Alternatively, the arrangement may be such that when a disk is held in the apparatus, the periphery of the disk is or is almost in contact with the support 5. It is also possible for the arrangement to be such that when a disk is installed on the apparatus it is held in a slightly flexed state and reverts to a flat shape when its engagement with the projections 4A is released.

[0039] Figure 3 shows a cross-sectional view of the apparatus shown in Figure 2 and shows a disk 10 held on the apparatus. This Figure shows the disk being held so that its periphery rests lightly on the supports 5 and the centre of the disk 10 is supported clear of the base portion 2 by the arms 1, preferably 2-3mm clear of the base portion 2.

[0040] The supports 5 also limit the extent by which the peripheral portion of the disk can be pressed towards the base portion. A further problem of the apparatus described in GB-A-2291640 is that by pressing the edge of the disk towards the base portion it is sometimes possible to prise the disk off the apparatus even though the button-like member has not been fully depressed. Accordingly, by limiting the scope for movement of the periphery of the disk towards the base portion, preferably in combination with an upstand (described further below) which limits the scope for lateral movement of the disk, this problem can be overcome or at least minimised.

[0041] The contact portions 4 may be mechanically interconnected, e.g. by a "living hinge" or a further button-like member. However, although this can be advantageous in some circumstances, it is not always possible or desirable. A living hinge can be formed between the contact portions if the apparatus is made of a resilient (typically crystalline) plastics material such as polypropylene and, indeed, this material is used to form apparatus as described herein when the apparatus is formed as an integral part of an enclosure for housing the disk. In some cases, such apparatus may, if desired, be provided with a mechanical interconnection between the contact portions, e.g. in the form of a living hinge, but in other cases no such interconnection is provided so the contact portions are separate from each other.

[0042] It is also desirable to form the apparatus described herein as an insert or "tray" for inserting within

a separate casing. The conventional "jewel box" mentioned above comprises a clear plastics casing with the disk-holding rosette formed on a tray inserted therein. The apparatus described herein may also be formed on a similar type of tray for inserting in a conventional clear plastics casing. Such inserts or trays are preferably made of an amorphous plastics material, such as styrene, as this has the required rigidity to hold its shape when formed into a relatively flat, tray-like article and is capable of being formed into more precise and intricate shapes. However, it is not always possible to form a living hinge that will survive repeated use in such a rigid material.

[0043] Accordingly, the apparatus described herein may also be provided in the form of an insert or tray formed from an amorphous plastics material with the respective contact portions 4 separate from each other but together forming a button-like member suitable for engagement by a finger tip. Nevertheless, in some circumstances, it is possible to form living hinges between the contact portions of apparatus formed of an amorphous plastics material.

[0044] An advantage of using contact portions 4 which are not interconnected, is that any tendency for one portion to pull the other one down if one portion is subjected to a lateral force such as A or C described above, is also avoided.

[0045] In such an arrangement, the contact portions 4 are also preferably shaped so as to increase the likelihood that both portions are contacted when the button-like member is depressed by a finger tip (as described above) to help ensure the release mechanism operates easily and reliably.

[0046] Another way of reducing the risk of accidental release of a disk due to forces applied in the plane of the disk, is to provide an upstand 6 surrounding or partially surrounding the disk when it is held in the apparatus so as to restrict access to the peripheral edge of the disk. The upstand 6 thus forms a "nest" in which the disk is held. The upstand 6 thus acts to obstruct access to much of the edge of the disk (except at finger cut-outs 6A which are provided to assist in lifting a disk out of the apparatus once it has been released) in order to further reduce the risk of forces being applied to the disk within the plane thereof. The upstand 6 is positioned close to the periphery of the disk (e.g. with a clearance of 0.5mm or less) so as to provide further restriction on the scope for movement of the disk within its own plane.

[0047] Such an upstand may be used in apparatus having any form of release mechanism, e.g. any of the forms illustrated in Figures 1 - 4 or described below with reference to Figures 8 - 13. The support 5 described above may be formed as a step in the side of the upstand 6.

[0048] In the arrangement shown in Figure 2, there is a gap in the upstand 6 at either side of the apparatus, each gap extending through about 40 degrees around the periphery of the disk. These gaps are provided to

reduce the width of the apparatus. This is, for example, required so the apparatus made in the form of an insert or tray can be fitted into an enclosure of conventional size. The disk is clearly more vulnerable to lateral forces in the area of these gaps. However, it will be appreciated that by shaping the contact portions 4 so that the ends of the gap between the contact portions fall on a line which does not coincide with the gaps in the upstand 6, this potential problem can be avoided. These gaps may also be closed by the sides of the container or its lid when this is closed. As the upstand 6 surrounds the majority of the disk and is positioned close thereto, it is still effective in reducing the scope for movement of the disk within its own plane despite the presence of these gaps. [0049] The apparatus described herein thus enables a disk to be securely held by simply placing the disk on the apparatus so that its aperture lies over the button-like member. The disk is then pressed towards the base portion 2 whereupon the button-like member is depressed causing the contact portions 4 and the projections 4A to move towards each other until the button-like member is able to pass through the aperture. Once the projections 4A have passed through the aperture, the arms 1 revert to or towards their unstressed position so that the projections 4A engage upon the outwardly facing surface of the disk and thus securely retain the disk on the apparatus.

[0050] The apparatus is designed so that the disk can be easily released by depressing the button-like member but is otherwise very difficult to remove other than by forcing it to the extent that the apparatus and/or the disk is damaged.

[0051] Whilst held by the apparatus, the disk is supported away from the base portion 2 by the arms 1 and/or the button-like member. As the arms flex principally about the hinge lines 3 which are at a greater radius from the centre of the apparatus than the projections 4A, any attempt to prise or wrench the disk off the apparatus will cause the arms 1 to flex further from the base portion about the hinge lines 3 and thus tighten their engagement with the disk.

[0052] The arms 1 themselves are preferably relatively stiff so movement thereof occurs principally by means of flexing about the hinge lines 3 rather than flexing of the arm itself or of the contact portions 4 relative to the arm 1.

[0053] As indicated above, the disk is released by simply depressing the button-like member whereby the arms 1 flex towards the base portion 2. The disk itself must also be allowed to move towards the base portion 2 with the arms until the projections 4A have moved inwards sufficiently to release their engagement on the outwardly facing surface of the disk.

[0054] As described above, the shape of the contact portions 4 of the button-like member and/or the provision of an upstand immediately adjacent the edge of the disk help to reduce the risk of the disk being accidentally released by forces applied in the plane of the disk.

[0055] The apparatus shown in Figure 2 is preferably formed as an integral, one-shot plastics moulding.

[0056] Further improvements and features of the upstand 6 will now be described.

5 [0057] As indicated above, the apparatus is provided with an upstand 6 for surrounding or partially surrounding a disk held in the apparatus so as to restrict access to the peripheral edge of the disk. The upstand 6 thus acts to obstruct access to much of the edge of the disk, except at finger cut-outs 6A which are provided to assist in lifting a disk out of the apparatus when it has been released, to reduce the risk of forces being applied to the disk within the plane thereof. The upstand 6 is preferably positioned close to the periphery of the disk (eg with a clearance of 0.5mm or less) so as to restrict the scope for movement of the disk within its own plane.

10 [0058] A potential problem with apparatus such as that shown in Figure 2 is that users unfamiliar with the apparatus may be tempted to use the finger recesses 6A to try to grip the edge of the disk and attempt to wrench the disk off the button-like member without depressing the button-like member 4 and in doing so they are likely to damage the disk and/or the apparatus.

15 [0059] Figure 5 is a schematic plan view of a finger recess 6A similar to those shown in Figure 2 but which is formed such that when a disk 10 is held in the apparatus a part 6B of the upstand 6 extending across the finger recess 6A prevents or inhibits access to the edge of the disk 10 so that a user cannot use the finger recess to attempt to grip the disk by its edges.

20 [0060] Figure 6A is a cross-sectional view of the finger recess 6A shown in Figure 5 and shows the position of the disk when it is held by the disk-engaging means. As shown, the disk is preferably held just clear of the step or support 5 provided on the inner side of the upstand 6 but is at a position level with or beneath the top of the part 6B. The upstand 6, and the parts 6B thereof across the recesses 6A thus prevent access to the edge of the disk.

25 [0061] However, after the disk has been released from the disk-engaging means by depression of the button-like member 4, an ejection mechanism (as described above) causes the disk to be lifted so it is supported on or slightly above the button-like member 4 so that the periphery of the disk stands proud of the upstanding portion 6B as shown in Figure 6B. The user can then make use of the finger recesses 6A to grip the edge of the disk 10 in order to lift it from the apparatus.

30 [0062] It will be appreciated that, compared to the arrangement shown in Figure 2, the finger recesses shown in Figure 5 are modified so that they do not extend through to the inner side of the upstand 6 so the upstand 6 is not interrupted by the recesses. This is achieved by providing a relatively thin wall or upstand 6B across the inner end of each finger recess 6A as shown in Figure 5.

35 [0063] Figure 7 is a plan view of apparatus similar to that shown in Figure 2 but with the addition of walls 6B

across the inner ends of the finger recesses 6A to prevent access to the periphery of the disk until the disk is lifted clear of the walls 6B following release of the disk-engaging means.

[0064] As described above, to enable the disk 10 to be lifted from the apparatus it must be moved to a raised position following its release so that it stands proud of the part 6B of the upstand 6. It is found that access to the edge of the disk is sufficient to enable it to be lifted, it not being necessary for the user's fingers to engage the underside of the disk. Thus, to enable the disk to be lifted away from the apparatus it is merely necessary for the disk to be moved, following its release from the disk-engaging means, to a position where it stands just clear of the top of parts 6B of the upstand 6, preferably with the underside of the disk 10 just clear of the top of parts 6B.

[0065] The top of the parts 6B of the upstand may be at the same level as the top of the remainder of the upstand 6 or may be at a slightly lower position than the top of the remainder of the upstand 6.

[0066] When the disk 10 is held by the disk-engaging means, the upper surface of the disk 10 preferably lies at substantially the same level as the top of the parts 6B or may lie slightly below the level of the top of the remainder of the upstand 6 to prevent access to the edge of the disk 10. However, in other arrangements, when the disk 10 is held by the disk-engaging means, its upper surface may lie at a higher level than the top of the parts 6B as the form of the upstand 6 and/or recesses 6A may be such as to prevent a user's finger from being able to grip the edge of the disk as only the upper corner at the periphery of the disk can be touched. However, following release of the disk 10, it is lifted so the bottom surface of the disk 10 lies at a similar level to or above the level of the top of the parts 6B so the edge of the disk 10 can be gripped by a user's fingers.

[0067] Figures 8 and 9 show a further embodiment of apparatus for holding a compact disk. This embodiment is designed for holding a digital video disc (DVD) and the base portion 2 thus has a shape and size similar to that of a conventional video box.

[0068] The disk release mechanism illustrated in Figures 8 and 9 is similar to that described in GB-A-2291640 and WO96/14636. The two halves of the button-like member may be joined by a living hinge as shown or may be unconnected.

[0069] The upstand 6 shown in Figures 8 and 9 is similar to that of Figure 2 except that it is continuous, i.e. it extends the full 360 degrees around the periphery of the disk and, in the arrangement shown, no finger recesses are provided.

[0070] A support 5 is provided in the form of a step on the inner edge of the upstand 6 as in Figure 2 except this is also continuous, i.e. extends the full 360 degrees around the periphery of the disk.

[0071] The apparatus shown in Figures 8 and 9 functions in a manner similar to that shown in Figure 2. When

a disk is held on the apparatus, the upstand, being positioned immediately adjacent the periphery of the disk, obstructs access to the edge of the disk to prevent forces being applied to the disk in the plane thereof and to inhibit finger access to the edge of the disk and also serves to restrict scope for movement of the disk within the plane of the disk. It is therefore very difficult for the disk to be released from the mechanism either accidentally or intentionally other than by depressing the button-like member 4 at the centre of the disk.

[0072] When the button-like member 4 is depressed, the centre of the disk is flexed downwards by the action of the projections 4A of the button-like member 4 as the periphery of the disk is supported on the support 5 until the engagement of the projections 4A on the disk are released and the button-like member is able to pass through the central hole of the disk. The centre of the disk then "pops up" as the disk reverts to its flat, unflexed state whereby the centre of the disk is raised to prevent it being re-engaged by the button-like member when the user's finger is removed therefrom. The disk then rests lightly on the top of the button-like member 4 and its projections 4A and in this position its edges are held clear of the upstand 6 so a user's fingers can engage the edges of the disk to lift it away from the apparatus.

[0073] Figures 10 and 11 show another embodiment of apparatus for holding a compact disk similar to that shown in Figures 8 and 9 but with a 3-arm release mechanism instead of a 2-arm release mechanism, and mounted on a substantially square base portion 2 rather than a rectangular base portion. As shown, the three arms 1 are equi-angularly spaced from each other.

[0074] Each of the three arms 1 is cantilevered from the base portion 2 and connected thereto at a hinge line 3. The inner ends of the three arms 1 together form a button-like member comprising a triangular portion 20 each side of which is connected to a segment-shaped portion 21 by a living hinge 22. The three segment-shaped portions 21 together form a substantially complete circular shape over which the central hole of a disk 10 can be fitted. A lip or projection 21A for engaging on the outwardly facing surface of the disk 10 projects from the curved side of each segment-shaped portion 21. The lips 21A preferably project 0.5 - 1.0mm from the portions 21.

[0075] Depression of the triangular portion 20 towards the base portion 2 causes the three segment-shaped portions 21 to move towards each other, i.e. towards the centre of the triangular portion 20, until the projections 4A are moved out of engagement with the outwardly facing surface of the disk 10 so as to release their engagement with the disk. In all other respects, this apparatus functions in a similar manner to that shown in Figures 8 and 9.

[0076] The base portions 2 shown in Figures 8 - 11 may form part of a casing or may form a tray for insertion into a casing. In a further arrangement, the base portion 2 may be affixed, e.g. by adhesive, to one half of a folded

cover (not shown) e.g. formed of cardboard, the other half being arranged, when folded over, to cover a disk held on the apparatus.

[0077] For the latter arrangement, the rear side of the base portion 2 is preferably substantially flat so as to facilitate its adhesion to the folded cover. The rear sides of the base portions shown in Figures 8 - 11 may be formed flat apart from a circular recess corresponding to the circular upstand 6 and a central cut-out where the release mechanism is formed.

[0078] A further upstand in the form of a wall 23 is provided around the periphery of the base portion 2. The wall 23 is preferably slightly higher than the upstand 6 so when the folded cover mentioned above is closed, the cover does not lie in contact with the disk. As shown in Figure 10, the wall 23 may form part of the upstand 6 where the upstand 6 meets the wall at the edge of the base portion.

[0079] Figure 12 is a plan view of another version of a 3-arm release mechanism which may be used in any of the other embodiments described above. In this case, the inner ends of the arms 1 are each provided with a sector-shaped portion 25 which together form a circular button-like member. The three sector-shaped portions 25 are separate from each other, i.e. they are not connected by living hinges. Each of the sector-shaped portions 25 has a projection 25A for engaging a disk.

[0080] Figure 13A is a perspective view of the 3-arm release mechanism shown in Figure 12. Figure 13B is a similar view but with the arms 1 and sector-shaped portions 25 omitted so as to more clearly show a three-armed re-inforcing portion 26 provided across the cut-out in the base portion 2 underneath the release mechanism.

[0081] The apparatus shown in Figures 10 and 11 is suitable for making in a resilient crystalline plastics material and the apparatus shown in Figures 12 and 13 is suitable for making in an amorphous plastics material.

[0082] In each of the embodiments described in relation to Figures 8 - 11, the upstand 6 is again preferably positioned so as to be immediately adjacent the edge of a disk held on the apparatus so as to prevent movement of the disk in its own plane and to provide the other functions described above.

[0083] Figures 8 - 11 show a continuous upstand 6 without finger recesses. However, in other arrangements (not shown) some areas of the upstand may be of slightly reduced height to facilitate finger access to the edge of the disk once it has been released so making it easier to grip the disk to lift it clear of the apparatus. Four localised areas of reduced height may, for instance, be provided in the upstand, each extending over a length of upstand subtending an angle of about 20 degrees at the centre of the apparatus. These areas are preferably equi-angularly spaced from each other and preferably located in areas of the upstand nearest the corners of the base portion 2.

[0084] In the apparatus described in relation to Fig-

ures 8 - 11, the support 5 preferably comprises a raised surface substantially parallel to the base portion (and to the plane of a disk held thereon). The raised surface may, for instance, be at a level 2 - 3mm above the base portion 2 and have a width of about 2mm. The upstand 6 extends about 0.5 to 1.5mm, and preferably about 1mm, above the raised surface 5 (a compact disk typically has a thickness of about 1 mm).

[0085] It should be noted that the degree of flexing of a disk required to cause the centre of the disk to rise or "pop up" sufficiently on release of the disk to prevent re-engagement thereof by the disk engaging mechanism may be relatively small. In some embodiments with a typical disk having a diameter of approximately 120mm the centre may be flexed approximately 0.5 - 1.0mm relative to the periphery thereof whereas in other embodiments the centre may flex 1.0 - 3.0mm. Similarly, the periphery of the disk need be raised by only a relatively small amount to lift it sufficiently relative to the upstand to enable the edges of the disk to be grasped. In some embodiments, this movement may be as small as 0.5 - 1.0mm whereas in other embodiments it may be 1 - 5mm.

Claims

1. Apparatus for holding a compact disk (10) having a central hole, the apparatus comprising: a base portion (2) provided with disk engaging and release means (1, 4, 4A) for releasably engaging the central hole of a disk; ejection means (1, 4, 4A, 5) for moving the disk to a raised position relative to the base portion following its release from the disk engaging means; **characterised by** an upstand (6) for surrounding the periphery of a disk (10) held on the apparatus, the upstand (6) being positioned and shaped to allow access to the edge of the disk (10) when it has been moved to the raised position following release from the disk engaging means to permit removal of the disk (10) from the apparatus but prevent such access when the disk is held by the disk engaging means.
2. Apparatus as claimed in Claim 1 in which the upstand includes a wall perpendicular to the base portion, the wall being positioned and shaped to be closely adjacent the periphery of the disk to prevent access to the periphery of the disk when the disk is held by the disk engaging means.
3. Apparatus as claimed in Claim 1 or 2 in which the upstand (6) is positioned so as to leave a clearance between itself and the periphery of a disk (10) held by the disk engaging means of 0.5 mm or less.
4. Apparatus as claimed in Claim 1, 2 or 3 arranged such that, when a disk (10) is held by the disk en-

- gaging means (1, 4, 4A), at least the underside of the disk (10) is held level with or beneath the top of the upstand (6) and, when the engagement with the disk engaging means is released, the disk (10) is lifted so its periphery stands proud of the top of the upstand (6) to allow a user's fingers to grip the edge of the disk.
5. Apparatus as claimed in any preceding Claim in which the ejection means comprise resilient means for lifting the disk (10) once the engagement of the disk engaging means (1, 4, 4A) with the disk (10) has been released.
 6. Apparatus as claimed in any of Claims 1 to 4 in which the ejection means comprises disk support means (5) provided on the base portion (2) for supporting the disk (10) at positions away from the central hole, the arrangement being such that, when the disk (10) is supporting by the disk support means (5), and the disk engaging means is depressed, the centre of the disk (10) is flexed such that upon release of the engagement of the disk engaging means (1, 4, 4A) with the disk (10), the disk (10) is able to revert to its unflexed state so the centre of the disk (10) moves out of engagement with the disk engaging means (1, 4, 4A).
 7. Apparatus as claimed in Claim 6 in which the disk support means comprises a step (5) provided on the inner side of the upstand (6).
 8. Apparatus as claimed in any of Claims 4 to 7 in which a plurality of recesses (6A) are provided in the upstand (6) to facilitate finger access to the periphery of a disk (10) once the disk (10) has been moved to the raised position.
 9. Apparatus as claimed in Claim 8 in which recesses (6A) comprise localised reductions in the height of the upstand (6).
 10. Apparatus as claimed in claim 8 or 9 in which a part (6B) of the upstand (6) is of reduced thickness relative to the remainder of the upstand (6) and extends across the inner side of each of the recesses (6A).
 11. Apparatus as claimed in Claim 10 in which the said part (6B) of the upstand (6) of reduced thickness is of similar height to the remainder of the upstand (6).
 12. Apparatus as claimed in any preceding claim in which the disk engaging means (1, 4, 4A) are arranged to be resiliently depressed toward the base portion (2) to release their engagement with the disk (10) and, following release of their engagement with the disk (10), move the disk (10) towards the raised position as they revert to their undepressed positions.
 13. Apparatus as claimed in any preceding claim in which the disk engaging means comprises at least two arms (1) resiliently cantilevered from the base portion (2), the inner ends of the arms (1) together forming a button-like member (4) and each being provided with a projection (4A) arranged to securely retain a compact disk (10) on the apparatus by engaging on an outwardly facing surface thereof, the arrangement being such that depression of the button-like member (4) depresses the arms (1) so as to move the projections (4A) towards each other until their engagement on the outwardly facing surface of the compact disk (10) is released.
 14. Apparatus as claimed in Claim 13 which the disk engaging means comprises two arms the inner end of each arm being provided with a contact portion (4), the contact portions together forming a button-like member (4), the contact portions (4) being arranged such that should a force be applied to a disk (10) held by the apparatus substantially in the plane of the disk and substantially perpendicular to the length of the arms (1), at least the majority of the said force is transmitted by the disk (10) to only one of the contact portions (4) so the possibility of such a force acting on the button-like member (4) so as to release the disk is reduced.
 15. Apparatus as claimed in Claim 14 in which the respective contact portions (4) are separated by a gap, the ends of the gap lying away from a line which is perpendicular to the length of the arms (1).
 16. Apparatus as claimed in Claim 15 in which a line joining the opposite ends of said gap lies at an angle of 45 to 70 degrees to the arms (1).
 17. Apparatus as claimed in Claim 15 or 16 in which said gaps forms a substantially straight dividing line between the contact portions (4).
 18. Apparatus as claimed in Claim 15 or 16 in which said gap forms a curved dividing line between the contact portions (4).
 19. Apparatus as claimed in Claim 18 in which said gap forms a substantially S-shaped dividing line between the contact portions (4).
 20. Apparatus as claimed in Claim 15, 16 or 17 in which said gaps forms a substantially V-shaped or U-shaped dividing line between the contact portions (4).
 21. Apparatus as claimed in Claim 15, 16, 18 or 20 in

- which said gap does not pass through the central region of the button-like member (4).
22. Apparatus as claimed in any of Claims 15 to 19 in which a portion of said gap passing through the central region of the button-like member (4) is not perpendicular to the arms (1). 5
23. Apparatus as claimed in any of Claims 15 to 20 in which the width of the gap is 1.5 mm or less and preferably 1.0 mm or less. 10
24. Apparatus as claimed in any Claims 1 to 13 in which the disk engaging means comprises three arms (1) resiliently cantilevered from the base portion. 15
25. Apparatus as claimed in Claim 24 comprising three equi-angularly spaced arms (1) each resiliently cantilevered from the base portion, the inner ends of the arms together forming a button-like member (20, 21, 25) for releasably engaging the central hole of the disk (10). 20
26. Apparatus as claimed in Claim 25 in which the base portion (2) has a substantially flat rear face. 25
27. Apparatus as claimed in Claim 26 in which the rear face of the base portion is affixed (2) to part of a folded cover. 30
28. Apparatus as claimed in Claim 25, 26 or 27 in which the button-like member comprises a triangular portion (20) each side of which is connected to a segment-shaped portion (21) provided at the inner end of each of the respective arms (1). 35
29. Apparatus as claimed in Claim 25, 26 or 27 in which the button-like member comprises three section-shaped portions (25) provided at the inner ends of the respective arms (1). 40
30. Apparatus as claimed in Claim 6 or any claim dependent thereon in which the support means (5) extended 360 degrees around the disk engaging means (1, 4, 4A). 45
31. Apparatus as claimed in Claim 6 or any claim dependent thereon in which the support means (5) is at a level 2 to 3 mm above the base portion (2).
32. Apparatus as claimed in Claim 26 or any claim dependent thereon in which the base portion (2) is square or rectangular and has an upstanding wall (23) around periphery thereof.
33. Apparatus as claimed in Claim 13 or any claim dependent thereon in which the projections (4A) project by between 0.5 and 1.0 mm.
34. Apparatus as claimed in Claim 33 in which each of the projections (4A) extend around an arc which subtends an angle of between 30 and 90 degrees with the centre of the apparatus.
35. Apparatus as claimed in any preceding claim arranged such that when the disk engaging means (1, 4, 4A) is depressed and a disk (10) is held on the apparatus, part of the apparatus and/or the disk (10) is flexed so that elastic energy is stored therein such that when the engagement of the disk engaging means with the disk (10) is released, said part and/or the disk (10) reverts to an unstressed state so as to cause at least the central portion of the disk (10) to move so the disk engaging means does not re-engage the disk when they revert to their undeformed position.
36. Apparatus as claimed in any preceding claim formed as one-piece moulding.
37. Apparatus as claimed in Claim 36 moulded from a resilient plastics material.
38. Apparatus as claimed in Claim 36 when dependent on Claim 12 in which the contact portions are mechanically interconnected.
39. Apparatus as claimed in Claim 26, 27 or 28 which is integrally moulded as part of an enclosure for a disk.
40. Apparatus as claimed in Claim 36 moulded from an amorphous plastics material.
41. Apparatus as claimed in Claim 40 when dependant upon Claim 12 in which the contact portions (4) are separate from each other.
42. Apparatus as claimed in Claim 40 or 41 in which the apparatus is in the form of an insert or tray for inserting into an enclosure.
43. Apparatus as claimed in any preceding claim having a compact disk (10) held thereon.

Patentansprüche

1. Apparatur zur Aufnahme von CDs (10) mit einem Mittelloch. Die Apparatur besteht aus: einer Basis-komponente (2) mit einer Einrast- und Auswurfvorrichtung für CDs (1, 4, 4A), wobei das Mittelloch der CD-Auswurfvorrichtung (1, 4, 4A, 5) lösbar einrastet, um die CD nach Freigabe aus der CD-Einrastvorrichtung aus der Basis-komponente herauszuheben; von einem Rand (6) gekennzeichnet, der die Peripherie einer in der Apparatur befindlichen CD

- (10) umgibt, wobei der Rand (6) so geformt und positioniert ist, dass auf den Rand der CD (10) zugegriffen werden kann, sobald diese nach Ausgabe aus der CD-Einrastvorrichtung angehoben wurde. Die CD (10) kann dann aus der Apparatur entnommen werden. Ein solcher Zugriff ist jedoch nicht möglich, solange die CD von der Einrastvorrichtung gehalten wird.
2. Apparatur nach Anspruch 1, bei der der Rand eine im rechten Winkel zur Basiskomponente stehende Wand umfasst, wobei die Wand so positioniert und geformt ist, dass sie sich unmittelbar an der Peripherie der CD befindet, damit auf die Peripherie der CD nicht zugegriffen werden kann, wenn die CD in der CD-Einrastvorrichtung aufbewahrt wird.
 3. Apparatur nach Anspruch 1 oder 2, bei der der Rand (6) so positioniert ist, dass zwischen dem Rand und der Peripherie der CD (10), die sich in der CD-Einrastvorrichtung befindet, ein Abstand von maximal 0,5 mm verbleibt.
 4. Apparatur nach Anspruch 1, 2 oder 3, die so konstruiert ist, dass zumindest die Unterseite einer CD (10), wenn sich eine solche in der Diskeinrastvorrichtung (1, 4, 4A) befindet, auf gleicher Höhe zum oberen Abschluss des Randes (6) oder darunter liegt. Wenn die Einrastung der CD-Einrastvorrichtung gelöst wird, wird die CD (10) angehoben, so dass ihre Peripherie über den oberen Abschluss des Randes (6) aufragt, damit der Nutzer den Rand der CD mit seinen Fingern erfassen kann.
 5. Apparatur nach einem der vorangehenden Ansprüche, bei der die Auswurfvorrichtung eine Federvorrichtung umfasst, die die CD (10) anhebt, sobald die Einrastung der CD-Einrastvorrichtung (1, 4, 4A) mit der CD (10) gelöst worden ist.
 6. Apparatur nach einem der Ansprüche 1 bis 4, bei der die Auswurfvorrichtung mit einer CD-Haltevorrichtungen (5) auf der Basiskomponente (2) versehen ist, um die CD (10) in Positionen, die sich nicht in der Nähe des Mittelochs befinden, zu stützen. Wird die CD (10) von der CD-Haltevorrichtung (5) gestützt und die CD-Einrastvorrichtung gedrückt, dann wird das Mittelstück der CD (10) so gebogen, dass die CD (10) bei Freigabe aus der CD-Einrastvorrichtung (1, 4, 4A) in ihren ungespannten Status zurückgehen kann und sich das Mittelstück der CD (10) aus der CD-Einrastvorrichtung (1, 4, 4A) löst.
 7. Apparatur nach Anspruch 6, bei der die CD-Haltevorrichtung einen Absatz (5) auf der Innenseite des Randes (6) enthält.
 8. Apparatur nach einem der Ansprüche 4 bis 7, bei der mehrere Aussparungen (6A) im Rand (6) enthalten sind, um den Zugriff mit den Fingern auf die Peripherie der CD (10) zu erleichtern, sobald die CD (10) emporgehoben wurde.
 9. Apparatur nach Anspruch 8, bei der die Aussparungen (6A) an manchen Stellen eine verringerte Höhe des Randes (6) umfassen.
 10. Apparatur nach Anspruch 8 oder 9, bei der ein Teil (6B) des Randes (6) im Verhältnis zum übrigen Rand (6) dünner ist und sich über die Innenseite jeder Aussparung (6A) erstreckt.
 11. Apparatur nach Anspruch 10, bei der der besagte Teil (6B) des Randes (6) mit verminderter Dicke eine ähnliche Höhe wie der übrige Rand (6) hat.
 12. Apparatur nach einem der vorangehenden Ansprüche, bei der die CD-Einrastvorrichtung (1, 4, 4A) federnd gegen die Basiskomponente (2) gedrückt werden muss, um deren Verbindung mit der CD (10) zu lösen und die CD (10) nach Freigabe durch Rückgang in den unkomprimierten Zustand emporzuheben.
 13. Apparatur nach einem der vorangehenden Ansprüche, bei der die CD-Einrastvorrichtung mindestens zwei auf der Basiskomponente (2) federnd gelagerte Arme (1) umfasst, wobei die Innenendstücke der Arme (1) miteinander ein knopfähnliches Teil (4) bilden und jeder mit einem Vorsprung (4A) zum sicheren Halten einer CD (10) in der Apparatur durch Einrasten der nach außen zeigenden Flächen versehen ist. Durch Drücken des knopfähnlichen Teils (4) werden die Arme (1) nach unten gedrückt und die Vorsprünge (4A) aufeinander zu bewegt, bis sich ihre Einrastung an der Außenfläche der CD (10) löst.
 14. Apparatur nach Anspruch 13, bei der die CD-Einrastvorrichtung aus zwei Armen besteht, wobei das Innenendstück jedes Arms mit einem Kontaktteil (4) versehen ist und die Kontaktteile zusammen ein knopfähnliches Teil (4) bilden. Die Kontaktteile (4) sind so angeordnet, dass sie, wenn auf eine in der Apparatur befindliche CD (10) Druck im Wesentlichen in der Ebene der CD und im Wesentlichen senkrecht zur Länge der Arme (1) ausgeübt wird, zumindest der Großteil des besagten Drucks von der CD (10) auf nur ein Kontaktteil (4) übertragen wird. Dadurch sinkt die Wahrscheinlichkeit, dass eine solche Kraft auf das knopfartige Teil (4) wirkt und die CD freigegeben wird.
 15. Apparatur nach Anspruch 14, bei der die entsprechenden Kontaktteile (4) durch eine Lücke getrennt sind und die Enden der Lücke von einer senkrecht zur Länge der Arme (1) befindlichen Linie abstehen.

16. Apparatur nach Anspruch 15, bei der eine Linie, welche die gegenüberliegenden Enden der besagten Lücke verbindet, einen Winkel zwischen 45 und 70 Grad zu den Armen (1) einnimmt.
17. Apparatur nach Anspruch 15 oder 16, bei der die besagte Lücke eine im Wesentlichen gerade Trennlinie zwischen den Kontaktteilen (4) bilden.
18. Apparatur nach Anspruch Punkt 15 oder 16, bei der die besagte Lücke eine gekrümmte Trennlinie zwischen den Kontaktteilen (4) bilden.
19. Apparatur nach Anspruch 18, bei der die besagte Lücke im Wesentlichen eine Trennlinie in S-Form zwischen den Kontaktteilen (4) bildet.
20. Apparatur nach Anspruch 15, 16 oder 17, bei der die besagte Lücke im Wesentlichen eine V- oder U-förmige Trennlinie zwischen den Kontaktteilen (4) bildet.
21. Apparatur nach Anspruch Punkt 15, 16, 18 oder 20, bei der die besagte Lücke nicht durch den Mittelbereich des knopfähnlichen Teils (4) läuft.
22. Apparatur nach Anspruch 15 bis 19, bei der ein Teil der besagten Lücke durch den Mittelbereich des knopfähnlichen Teils (4), aber nicht im rechten Winkel zu den Armen (1) verläuft.
23. Apparatur nach Anspruch Punkt 15 bis 20, bei der die Breite der Lücke höchstens 1,5 mm und vorzugsweise höchstens 1,0 mm beträgt.
24. Apparatur nach Anspruch Punkt 1 bis 13, bei der die CD-Einrastvorrichtung drei auf der Basiskomponente federnd gelagerte Arme (1) umfasst.
25. Apparatur nach Anspruch Punkt 24 mit drei gleichwinklig angeordneten Armen (1), jeder federnd auf der Basiskomponente gelagert, wobei die Innenendstücke der Arme zusammen ein knopfähnliches Teil (20, 21, 25) zum lösbaren Einrasten des Mittellochs der CD (10) bilden.
26. Apparatur nach Anspruch 25, bei der die Basiskomponente (2) im Wesentlichen eine flache Rückseite hat.
27. Apparatur nach Anspruch 26, bei der die Rückseite der Basiskomponente (2) mit einem Teil einer gefalteten Abdeckung verbunden ist.
28. Apparatur nach Anspruch 25, 26 oder 27, bei der das knopfähnliche Teil ein dreieckiges Teil (20) enthält, von dem jede Seite mit einem segmentförmigen Teil (21) verbunden ist, das sich am Innenendstück des jeweiligen Arms (1) befindet.
29. Apparatur nach Anspruch 25, 26 oder 27, bei der das knopfähnliche Teil drei sektionsförmige Teile (25) enthält, die sich am Innenendstück des jeweiligen Arms (1) befinden.
30. Apparatur nach Anspruch 6 oder einer davon abhängigen Anspruch, bei der sich die Haltevorrichtung (5) auf 360 Grad um die CD-Einrastvorrichtung (1, 4, 4A) erstreckt.
31. Apparatur nach Anspruch 6 oder einer davon abhängigen Anspruch, bei der sich die Haltevorrichtung (5) auf einer Ebene von 2 bis 3 mm über der Basiskomponente (2) befindet.
32. Apparatur nach Anspruch 26 oder einer davon abhängigen Anspruch, bei der die Basiskomponente (2) quadratisch oder rechteckig ist und eine aufragende Wand (23) um die Peripherie hat.
33. Apparatur nach Anspruch 13 oder einer davon abhängigen Anspruch, bei der die Vorsprünge (4A) zwischen 0,5 und 1,0 mm vorstehen.
34. Apparatur nach Anspruch 33, bei der sich jeder Vorsprung (4A) um einen Bogen erstreckt, der einen Winkel zwischen 30 und 90 Grad mit dem Mittelstück der Apparatur bildet.
35. Apparatur nach einem der vorangehenden Ansprüche, die so angeordnet ist, dass ein Teil der Apparatur bzw. die CD (10) gebogen wird, wenn die CD-Einrastvorrichtung (1, 4, 4A) gedrückt ist und sich eine CD (10) in der Apparatur befindet, so dass darin elastische Energie gespeichert wird und das besagte Teil bzw. die Disk (10) in ihren ungespannten Zustand zurückgelangt, wenn die Einrastung der CD-Einrastvorrichtung mit der CD (10) gelöst wird, wodurch mindestens das Mittelstück der CD (10) auf eine Weise bewegt wird, dass die CD-Einrastvorrichtung nicht wieder mit der CD einrastet, wenn diese in ihre ursprüngliche, ungespannte Position zurückkehrt.
36. Apparatur nach einem der vorangehenden Ansprüche als einteiliges Formteil.
37. Apparatur nach Anspruch 36 aus elastischem Plastikmaterial geformt.
38. Apparatur nach Anspruch 36, wenn von Anspruch 12 abhängig, bei der die Kontaktteile mechanisch miteinander verbunden sind.
39. Apparatur nach Anspruch 26, 27 oder 28, die als Teil einer CD-Umfassung integral geformt ist.

40. Apparatur nach Anspruch 36, aus amorphem Plastikmaterial geformt.
41. Apparatur nach Anspruch 40, wenn von Anspruch 12 abhängig, in der die Kontakteile (4) voneinander getrennt sind.
42. Apparatur nach Anspruch Punkt 40 oder 41 in Form eines Einsatzes oder Trägers zum Einschieben in ein Gehäuse.
43. Apparatur nach einem der vorangehenden Ansprüche mit einer eingelegten CD (10).

Revendications

1. Appareil pour retenir un disque compact (10) comportant un orifice central, l'appareil comprenant : une partie de base (2) pourvue d'un moyen de prise et de libération de disque (1, 4, 4A) pour venir en prise de manière libérable avec l'orifice central d'un moyen d'éjection de disque (1, 4, 4A, 5) pour déplacer le disque dans une position dressée par rapport à la partie de base à la suite de sa libération du moyen de prise de disque ; caractérisé par un rebord (6) pour entourer la périphérie d'un disque (10) retenu sur l'appareil, le rebord (6) étant positionné et formé de manière à permettre l'accès au bord du disque (10) lorsqu'il a été déplacé dans la position dressée à la suite de la libération du moyen de prise de disque pour permettre le retrait du disque (10) de l'appareil mais à empêcher un tel accès lorsque le disque est retenu par le moyen de prise de disque.
2. Appareil suivant la revendication 1, dans lequel le rebord comprend une paroi perpendiculaire à la partie de base, la paroi étant positionnée et formée de manière à être très proche de la périphérie du disque pour empêcher l'accès à la périphérie du disque lorsque le disque est retenu par le moyen de prise de disque.
3. Appareil suivant la revendication 1 ou 2, dans lequel le rebord (6) est positionné de manière à laisser un dégagement entre lui et la périphérie d'un disque (10) retenu par le moyen de prise de disque de 0,5 mm ou moins.
4. Appareil suivant la revendication 1, 2 ou 3, agencé de manière à ce que, lorsqu'un disque (10) est retenu par le moyen de prise de disque (1, 4, 4A), au moins le dessous du disque (10) est retenu au niveau ou en dessous du sommet du rebord (6) et, lorsque la prise avec le moyen de prise de disque est libérée, le disque (10) est soulevé de manière à ce que sa périphérie dépasse du sommet du rebord

(6) pour permettre aux doigts d'un utilisateur de saisir le bord du disque.

5. Appareil suivant l'une quelconque des revendications précédentes, dans lequel le moyen d'éjection comprend un moyen élastique pour soulever le disque (10) une fois que la prise du moyen de prise de disque (1, 4, 4A) avec le disque a été libérée.
6. Appareil suivant l'une quelconque des revendications 1 à 4, dans lequel le moyen d'éjection comprend un moyen de support de disque (5) prévu sur la partie de base (2) pour supporter le disque (10) dans des positions s'éloignant de l'orifice central, l'agencement étant tel que, lorsque le disque (10) est supporté par le moyen de support de disque (5), et que le moyen de prise de disque est enfoncé, le centre du disque (10) fléchit de telle sorte que, lors de la libération de la prise du moyen de prise de disque (1, 4, 4A) avec le disque (10), le disque (10) est capable de reprendre son état non fléchi de manière à ce que le centre du disque (10) vienne hors prise avec le moyen de prise de disque (1, 4, 4A).
7. Appareil suivant la revendication 6, dans lequel le moyen de support de disque comprend un palier (5) prévu sur le côté intérieur du rebord (6).
8. Appareil suivant l'une quelconque des revendications 4 à 7, dans lequel une pluralité d'évidements (6A) sont prévus dans le rebord (6) pour faciliter l'accès des doigts à la périphérie d'un disque (10) une fois que le disque (10) a été déplacé dans la position dressée.
9. Appareil suivant la revendication 8, dans lequel des évidements (6A) comprennent des réductions localisées dans la hauteur du rebord (6).
10. Appareil suivant la revendication 8 ou 9, dans lequel une partie (6B) du rebord (6) est d'épaisseur réduite par rapport au reste du rebord (6) et s'étend à travers le côté intérieur de chacun des évidements (6A).
11. Appareil suivant la revendication 10, dans lequel la dite partie (6B) du rebord (6) d'épaisseur réduite est de hauteur similaire au reste du rebord (6).
12. Appareil suivant l'une quelconque des revendications précédentes, dans lequel le moyen de prise de disque (1, 4, 4A) est propre à être enfoncé de manière élastique vers la partie de base (2) pour libérer sa prise avec le disque (10) et, à la suite de la libération de sa prise avec le disque (10), à déplacer le disque (10) vers la position dressée lorsqu'il reprend sa position non enfoncée.

13. Appareil suivant l'une quelconque des revendications précédentes, dans lequel le moyen de prise de disque comprend au moins deux bras (1) élastiquement en porte-à-faux par rapport à la partie de base (2), les extrémités intérieures des bras (1) formant ensemble un élément en forme de bouton (4) et étant chacune pourvue d'une saillie (4A) propre à retenir solidement un disque compact (10) sur l'appareil en venant en prise sur une surface tournée vers l'extérieur de celui-ci, l'agencement étant tel que l'enfoncement de l'élément en forme de bouton (4) enfonce les bras (1) de manière à déplacer les saillies (4A) l'une vers l'autre jusqu'à ce que leur prise sur la surface tournée vers l'extérieur du disque compact (10) soit libérée.
14. Appareil suivant la revendication 13, dans lequel le moyen de prise de disque comprend deux bras, l'extrémité intérieure de chaque bras étant pourvue d'une partie de contact (4), les parties de contact formant ensemble un élément en forme de bouton (4), les parties de contact (4) étant agencées de telle sorte que, si une force devait être exercée sur un disque (10) retenu par l'appareil pratiquement dans le plan du disque et pratiquement perpendiculairement à la longueur des bras (1), au moins la majorité de ladite force serait transmise par le disque (10) à une seule des parties de contact (4) de sorte que la possibilité qu'une telle force agisse sur l'élément en forme de bouton (4) de manière à libérer le disque soit réduite.
15. Appareil suivant la revendication 14, dans lequel les parties de contact (4) respectives sont séparées par un intervalle, les extrémités de l'intervalle se trouvant à l'écart d'une ligne qui est perpendiculaire à la longueur des bras (1).
16. Appareil suivant la revendication 15, dans lequel une ligne joignant les extrémités opposées dudit intervalle se trouve à un angle de 45 à 70 degrés des bras (1).
17. Appareil suivant la revendication 15 ou 16, dans lequel ledit intervalle forme une ligne de séparation pratiquement droite entre les parties de contact (4).
18. Appareil suivant la revendication 15 ou 16, dans lequel ledit intervalle forme une ligne de séparation courbe entre les parties de contact (4).
19. Appareil suivant la revendication 18, dans lequel ledit intervalle forme une ligne de séparation pratiquement en forme de S entre les parties de contact (4).
20. Appareil suivant la revendication 15, 16 ou 17, dans lequel ledit intervalle forme une ligne de séparation pratiquement en forme de V ou de U entre les parties de contact (4).
21. Appareil suivant la revendication 15, 16, 18 ou 20, dans lequel ledit intervalle ne traverse pas la région centrale de l'élément en forme de bouton (4).
22. Appareil suivant l'une quelconque des revendications 15 à 19, dans lequel une partie dudit intervalle traversant la région centrale de l'élément en forme de bouton (4) n'est pas perpendiculaire aux bras (1).
23. Appareil suivant l'une quelconque des revendications 15 à 20, dans lequel la largeur de l'intervalle est de 1,5 mm ou moins et de préférence de 1 mm ou moins.
24. Appareil suivant l'une quelconque des revendications 1 à 13, dans lequel le moyen de prise de disque comprend trois bras (1) élastiquement en porte-à-faux par rapport à la partie de base.
25. Appareil suivant la revendication 24, comprenant trois bras espacés de manière équiangle (1) chacun élastiquement en porte-à-faux par rapport à la partie de base, les extrémités intérieures des bras formant ensemble un élément en forme de bouton (20, 21, 25) pour venir en prise de manière libérable avec l'orifice central du disque (10).
26. Appareil suivant la revendication 25, dans lequel la partie de base (2) comporte une face arrière pratiquement plane.
27. Appareil suivant la revendication 26, dans lequel la face arrière de la partie de base est fixée (2) à une partie d'un couvercle replié.
28. Appareil suivant la revendication 25, 26 ou 27, dans lequel l'élément en forme de bouton comprend une partie triangulaire (20) dont chaque côté est relié à une partie en forme de segment (21) prévue à l'extrémité intérieure de chacun des bras respectifs (1).
29. Appareil suivant la revendication 25, 26 ou 27, dans lequel l'élément en forme de bouton comprend trois parties en forme de section (25) prévues aux extrémités intérieures des bras respectifs (1).
30. Appareil suivant la revendication 6 ou l'une quelconque des revendications dépendantes de celle-ci, dans lequel le moyen de support (5) s'étend sur 360 degrés autour du moyen de prise de disque (1, 4, 4A).
31. Appareil suivant la revendication 6 ou l'une quelconque des revendications dépendantes de celle-

ci, dans lequel le moyen de support (5) est à un niveau 2 à 3 mm au-dessus de la partie de base (2).

quel l'appareil se présente sous la forme d'un insert ou d'un plateau à insérer dans un boîtier.

32. Appareil suivant la revendication 26 ou l'une quelconque des revendications dépendantes de celle-ci, dans lequel la partie de base (2) est carrée ou rectangulaire et comprend une paroi dressée (23) autour de la périphérie de celle-ci. 5
33. Appareil suivant la revendication 13 ou l'une quelconque des revendications dépendantes de celle-ci, dans lequel les saillies (4A) font saillie entre 0,5 et 1 mm. 10
34. Appareil suivant la revendication 33, dans lequel chacune des saillies (4A) s'étend autour d'un arc qui sous-tend un angle compris entre 30 et 90 degrés par rapport au centre de l'appareil. 15
35. Appareil suivant l'une quelconque des revendications précédentes, agencé de sorte que lorsque le moyen de prise de disque (1, 4, 4A) est enfoncé et qu'un disque (10) est retenu sur l'appareil, une partie de l'appareil et/ou le disque (10) fléchit de telle sorte que l'énergie élastique est absorbée par celui-ci de sorte que, lorsque la prise du moyen de prise de disque avec le disque (10) est libérée, ladite partie et/ou le disque (10) revient à un état non contraint de manière à amener le déplacement d'au moins la partie centrale du disque (10) de telle sorte que le moyen de prise de disque ne revient pas en prise avec le disque lorsqu'il reprend sa position non enfoncée. 20 25 30
36. Appareil suivant l'une quelconque des revendications précédentes formé en un moulage d'une seule pièce. 35
37. Appareil suivant la revendication 36 moulé à partir d'un matériau en plastique élastique. 40
38. Appareil suivant la revendication 36 lorsqu'elle dépend de la revendication 12, dans lequel les parties de contact sont reliées entre elles de manière mécanique. 45
39. Appareil suivant la revendication 26, 27 ou 28 qui est intégralement moulé pour faire partie d'un boîtier pour un disque. 50
40. Appareil suivant la revendication 36 moulé à partir d'un matériau en plastique amorphe. 55
41. Appareil suivant la revendication 40 lorsqu'elle dépend de la revendication 12, dans lequel les parties de contact (4) sont séparées l'une de l'autre.
42. Appareil suivant la revendication 40 ou 41, dans le-
